Abstract

This paper describes a formalisation in Coq of nominal syntax extended with associative (A), commutative (C) and associative-commutative (AC) operators. This formalisation is based on a natural notion of nominal α-equivalence, avoiding the use of an auxiliary *weak* α-relation used in previous formalisations of nominal AC equivalence. A general α-relation between terms with A, C and AC function symbols is specified and formally proved to be an equivalence relation. As corollaries, one obtains the soundness of α-equivalence modulo A, modulo C and modulo AC operators. General α-equivalence problems with A operators are log-linearly bounded in time while if there are also C operators they can be solved in $O(n^2 \log n)$; nominal α-equivalence problems that also include AC operators can be solved with the same running time complexity as in standard first-order AC approaches.

This development is a first step towards verification of nominal matching, unification and narrowing algorithms modulo equational theories in general.

AC axioms.

1. Introduction

Equational problems are first-order formulas involving only one predicate: equality. Checking the validity of equational problems is a fundamental issue in automatic deduction. In this paper we focus on a particular class of equational problems: universally quantified conjunctions of equations. We aim at checking their validity modulo equational theories such as *α-equivalence, commutativity, associativity, idempotence*, etc. More generally, we consider nominal syntax instead of first-order syntax (to take into account binding operators) and assume that some function symbols obey equational axioms.

The notions of binding and α-equivalence play a fundamental role in programming languages and computation models. For example, in the *λ-calculus* [1], α-equivalence captures the notion of irrelevance of the names used as *bound variables*. At a first glance it seems to be an abstract problem but concrete examples can be provided in different syntactic computational frameworks, where a simple *renaming* of variables results in syntactically different but α-equivalent expressions. The simplest example in the λ-calculus is given by α-equivalent terms for the identity: $\lambda x.x \approx_\alpha \lambda y.y$; also, in computational languages it is enough to rename the names of the parameters of a function definition to obtain α-equivalent definitions.

Adequate manipulation of bound variables was a main motivation for the development of Nominal Logic [2] and it was taken as the basis of a series of formal developments including, *nominal unification* [3, 4, 5, 6, 7], that is, unification modulo $\approx_\alpha$, *nominal rewriting* [8, 9, 10], *deduction systems* [11], *programming languages* [12, 13, 14] and *reasoning frameworks* [15, 16].

In nominal syntax, instead of variables one uses *atoms* that are distinguished by their names and used to build abstractions. Additionally, the notion of *freshness* is made explicit through inference rules that define whether atoms are *free* or not in a nominal term. *Renaming* of variables is defined through *swappings* of atoms that are essential components of *permutations acting* over terms. Finally, the notion of α-equivalence is axiomatised through inference rules that specify whether, under some freshness constraints, terms are α-equivalent or not. This differs from the usual treatment in frameworks such as the λ-calculus, where α-equivalence is implicitly abstracted through assumptions such as Barendregt's variable convention [1].

The best known and most complete formal development of nominal syntax was specified in Isabelle/HOL by Urban et al. ([6, 7]): firstly, a relation $\approx_\alpha$ is specified and proved to be sound, that is, proved to be an equivalence relation; secondly, a nominal unification algorithm is specified, which uses α-equivalence, and verified to be correct and complete. In particular, in [6], Urban describes in detail how to prove that the nominal $\approx_\alpha$ relation is in fact an equivalence relation using an intermediate *weak* α-relation denoted as $\sim_\omega$. This technique was introduced by Kumar and Norrish [4] in a HOL4 formalisation of nominal unification, and was also applied in a previous version of our formalisation as reported in [17]. In this paper, we present an even simpler proof, avoiding formalisations of properties of this weak intermediate relation. This is obtained following the analytic scheme of proof shown in [8] and first applied in the PVS formalisation of nominal unification in [5].

Contribution. This paper describes a formalisation in the Coq proof assistant of the soundness of α-equivalence in nominal syntax. The distinguishing feature of this development is that we advance further and also check nominal α-equivalence with combinations of A, C and AC operators. The development can be enlarged with other equational theories. The main steps of the formalisation are described below.

- Initially, the notion of α-equivalence $\approx_\alpha$ was specified and proved to be sound. Although this property is usually taken for granted, its formalisation is not straightforward, since it relies on a non trivial induction on terms in which the induction hypothesis cannot be directly established for *convenient (α) renaming of proper sub-terms of the term to which the induction is applied.* Other crucial, but non-trivial properties are necessary: *preservation of freshness*, *equivariance* of $\approx_\alpha$, preservation of the action of *permutations*, etc.

- Then, α-equivalence with A, C and AC operators, denoted as $\approx_{\{A,C,AC\}}$, was specified and proved sound. The soundness of α-equivalence modulo A ($\approx_{\alpha,A}$), C ($\approx_{\alpha,C}$) and modulo AC ($\approx_{\alpha,AC}$) are inferred from the soundness of $\approx_{\{A,C,AC\}}$. These relations are specified in a parameterised manner, which will simplify the treatment and combination of α-equivalence modulo other equational theories. More precisely, the set of countable function symbols used to build terms in nominal syntax is annotated using *scripts*: A *superscript* distinguishes the equational properties of the operator, and a *subscript* gives the index of the function symbol in the class of symbols with the same equational properties; thus, for

instance, f_k^{AC} denotes the k^{th} AC function symbol in the signature. The relation $\approx_{\{A,C,AC\}}$ is defined using the rules of α-equivalence and it is proved that restricting it to α-equivalence corresponds to $\approx_\alpha$. Thus, using correctness of $\approx_\alpha$, the relation $\approx_{\{A,C,AC\}}$ is checked by applying the algebraic properties of A, C and AC operators and, in addition properties of *preservation of freshness* and *equivariance* for $\approx_{\{A,C,AC\}}$.

In addition, a naive decision algorithm for $\approx_{\{A,C,AC\}}$, based on the Coq specification, was implemented in OCaml and experiments were performed over randomly generated equational problems. When checking equivalence, the decision whether one should or should not apply nominal inference rules specialised for A, C or AC symbols is done in a natural manner using the superscript of the function symbols.

Regarding complexity, assuming a pre-computation of the flat form of terms headed with A and AC function symbols, and efficient data structures for manipulation of nominal terms and permutations, such as those used for the implementation of nominal α-equivalence and matching in [18], the following results are proved:

- Deciding α-equivalence modulo A only is log-linear in time on the size of the problem (i.e., $O(n \log n)$);
- If there are only A operators and C operators, then the complexity is $O(n^2 \log n)$; and
- α-equivalence modulo (A, C and) AC can be decided by adapting the algorithm presented by Benanav, Kapur and Narendran [19] for the case of pure AC-equivalence in standard first-order syntax, obtaining an $O(n^4 \log n)$ upper bound.

Outline. Section 2 presents necessary background on nominal abstract syntax. Sections 3 and 4 respectively present the formalisations of soundness of α-equivalence and its version with A, C and AC operators. Section 5 discusses experiments with an OCaml implementation extracted directly from the formalisation, and gives complexity bounds for the problem of deciding $\approx_{\{A,C,AC\}}$. Before concluding, Section 6 presents related work. The Coq specification is available at `http://ayala.mat.unb.br/publications.html`.

2. Nominal Syntax

This section presents necessary notions and notations of nominal syntax [8]. Given a signature Σ of function symbols and $\mathcal{V}$ and $\mathcal{A}$ countably infinite sets of *variables* and *atoms*, the set $\mathcal{T}(\Sigma, \mathcal{A}, \mathcal{V})$ of *nominal terms* is generated by the following grammar:

$$s, t \ ::= \ \langle\rangle \ \mid \ \overline{a} \ \mid \ [a]t \ \mid \ \langle s, t\rangle \ \mid \ f_k^E\, t \ \mid \ \pi.X$$

Atoms are the simplest structure, just object-level variables $a \in \mathcal{A}$. Atoms only differ in their names, so for atoms a and b the expression $a \neq b$ is redundant. A *permutation* is a bijection on $\mathcal{A}$ with a finite domain. A *swapping* is defined as a pair of atoms $(a\, b)$ and a *permutation* π is represented by a finite list of *swappings* of the form $(a_1\, b_1) :: \ldots :: (a_n\, b_n) :: \mathit{nil}$, where *nil* denotes the identity permutation. The composition of permutations π and π' is denoted as $\pi' \oplus \pi$. Unary permutations $(a\, b) :: \mathit{nil}$ will be abbreviated as $(a\, b)$. A variable $X \in \mathcal{V}$ as a term object should always be decorated by some permutation π *suspended* on X, $\pi.X$. For brevity, terms of the form $\mathit{nil}.X$ will be written as X.

Definition 1. *The* size *of a term t, denoted as $|t|$, is recursively defined as:*

$$|[a]t| \ := \ |t| + 1, \quad |\langle u, v\rangle| \ := \ |u| + |v| + 1, \quad |f_k^E\, s| \ := \ |s| + 1, \quad \_ \ := \ 1.$$

Permutations *act* on nominal terms, but suspend over variables. The *empty tuple* or *unit* is denoted as $\langle\rangle$ and non empty tuples are built using *pairs* of terms of the form $\langle s, t\rangle$, where s and t might be also pairs. Notice that this syntax does not allow construction of unary tuples. The notation $\overline{a}$ represents the atom a as a term object. $[a]t$ is an *abstraction* of an atom a in a term t. The notation $f_k^E\, t$ represents the *application* of $f_k^E \in \Sigma$ to t. The scripts E and k in the function symbol f_k^E are respectively used to distinguish the equational properties of the function symbol and the indexation of the function symbol between the class of operators with the same equational properties. These scripts will be omitted when no confusion arises.

```
Inductive term : Set :=
  | Ut : term
  | At : Atom → term
  | Ab : Atom → term → term
  | Pr : term → term → term
  | Fc : nat → nat → term → term
  | Su : Perm → Var → term

Notation <<>> := (Ut).
Notation %a := (At a).
Notation [a]^t := (Ab a t).
Notation <|t1,t2|> := (Pr t1 t2).
Notation pi|.X := (Su pi X).
```

In the Coq specification the grammar is written as above. Operators `Ut, At, Ab, Pr, Fc` and `Su` specify the unit, atoms as term objects, abstractions, pairs, function applications and suspended variables, respectively. For the `Fc` constructor, the first and second `nat` arguments represent the super and subscripts of the applied function symbol. In the formalisation, the function symbols f_j^A and f_k^{AC} are represented respectively by `Fc 0 j` and `Fc 1 k`, both having type `term` $\rightarrow$ `term`. All other superscripts are representing the empty equational theory.

Notice that in Coq, an atom as an object term $\overline{a}$, is written `(At a)`. Notice also that although in nominal syntax two atoms a and d are different by definition, `(At a)` and `(At d)` could be the same atom, since in the Coq specification a and d are used as meta-variables ranging over atoms.

Definition 2. *The* action *of a permutation over terms is specified as the homeomorphic extension of the action of lists of swappings over single atoms:*

$$\begin{array}{llll} \pi \cdot \langle\rangle := \langle\rangle & \pi \cdot \langle u, v\rangle := \langle \pi \cdot u, \pi \cdot v\rangle & \pi \cdot f_k^E\, t := f_k^E\,(\pi \cdot t) \\ \pi \cdot \overline{a} := \overline{\pi \cdot a} & \pi \cdot ([a]t) := [\pi \cdot a](\pi \cdot t) & \pi \cdot (\pi'\,.\,X) := (\pi' \oplus \pi)\,.\,X \end{array}$$

The action of a permutation over an atomic term object $\overline{a}$, e.g., $\pi \cdot \overline{a}$, gives as result a term $\overline{\pi \cdot a}$. This is specified as $\pi \cdot$ (`At` a), which gives as result `At` $(\pi \cdot a)$, and not the atom $\pi \cdot a$.

The action of the permutation π over the suspended variable $\pi'.X$ gives as result the term $\pi \cdot (\pi'.X) = (\pi' \oplus \pi).X$. Notice that permutation composition works in the opposite direction.

Example 1. *The permutation* $(a\ b) :: \pi$ *acting over the term* $[a]\langle \overline{b}, \pi'.X\rangle$ *will have as result* $[\pi \cdot b]\langle \overline{\pi \cdot a}, (\pi' \oplus ((a\ b) :: \pi)).X\rangle$.

2.1. Freshness and $\boldsymbol{\alpha}$*-equivalence*

The native notion of equality on nominal terms is α-equivalence, which is defined using *swappings* and a notion of freshness. A *freshness constraint* is a pair $a \# t$ of an atom and a nominal term t. Intuitively, $a \# t$ means that a is fresh in t, that is, if a occurs in t then it must do so under an abstractor $[a]$. An *α-equality constraint* is a pair $s \approx_\alpha t$ of two terms s and t. A *freshness context*, is a set of *freshness constraints* whose elements are restricted to pairs $a\#X \in \mathcal{A} \times \mathcal{V}$. ∇ will range over freshness contexts. A *freshness judgement* is a tuple of the form $\nabla \vdash a \# t$, whereas an *α-equivalence judgement* is a tuple of the form $\nabla \vdash s \approx_\alpha t$.

$$\frac{}{\nabla \vdash a \# \langle\rangle}\,(\#\langle\rangle) \qquad \frac{}{\nabla \vdash a \# \bar{b}}\,(\#\,\mathbf{atom}) \qquad \frac{\nabla \vdash a \# t}{\nabla \vdash a \# f_k^E\, t}\,(\#\,\mathbf{app}) \qquad \frac{}{\nabla \vdash a \# [a]t}\,(\#\,\mathbf{a[a]})$$

$$\frac{\nabla \vdash a \# t}{\nabla \vdash a \# [b]t}\,(\#\,\mathbf{a[b]}) \qquad \frac{(\pi^{-1} \cdot a \# X) \in \nabla}{\nabla \vdash a \# \pi.X}\,(\#\,\mathbf{var}) \qquad \frac{\nabla \vdash a \# s \;\; \nabla \vdash a \# t}{\nabla \vdash a \# \langle s, t\rangle}\,(\#\,\mathbf{pair})$$

Figure 1: Rules for the freshness relation

The *derivable* freshness and α-equivalence judgements are defined by the rules in Figures 1 and 2. We write $ds(\pi, \pi')\#X$ as an abbreviation of $\{a \# X \mid a \in ds(\pi, \pi')\}$, where $ds(\pi, \pi') = \{a \mid \pi \cdot a \neq \pi' \cdot a\}$ is the set of atoms where π and π' differ (the *difference set*). A set $\mathcal{P}$ of constraints is called a *problem*. We write $\nabla \vdash \mathcal{P}$ when proofs of the judgment $\nabla \vdash P$ exist for each $P \in \mathcal{P}$, using rules of Figures 1 and 2.

$$\frac{}{\nabla \vdash \langle\rangle \approx_\alpha \langle\rangle}\,(\approx_\alpha \langle\rangle) \qquad \frac{}{\nabla \vdash \overline{a} \approx_\alpha \overline{a}}\,(\approx_\alpha \mathbf{atom}) \qquad \frac{\nabla \vdash s \approx_\alpha t}{\nabla \vdash f_k^E\, s \approx_\alpha f_k^E\, t}\,(\approx_\alpha \mathbf{app})$$

$$\frac{\nabla \vdash s \approx_\alpha t}{\nabla \vdash [a]s \approx_\alpha [a]t}\,(\approx_\alpha [\mathbf{aa}]) \qquad \frac{\nabla \vdash s \approx_\alpha (a\,b) \cdot t \;\; \nabla \vdash a \# t}{\nabla \vdash [a]s \approx_\alpha [b]t}\,(\approx_\alpha [\mathbf{ab}])$$

$$\frac{ds(\pi, \pi')\#X \subseteq \nabla}{\nabla \vdash \pi.X \approx_\alpha \pi'.X}\,(\approx_\alpha \mathbf{var}) \qquad \frac{\nabla \vdash s_0 \approx_\alpha t_0 \;\; \nabla \vdash s_1 \approx_\alpha t_1}{\nabla \vdash \langle s_0, s_1\rangle \approx_\alpha \langle t_0, t_1\rangle}\,(\approx_\alpha \mathbf{pair})$$

Figure 2: Rules for the relation $\approx_\alpha$

The interesting rules for freshness are those for abstractions and suspensions. For example, $\nabla \vdash a \# \langle [a](\langle \overline{a}, \overline{b}\rangle), \pi.X\rangle$ can be derived only if the pair $\pi^{-1} \cdot a\#X$ is in the context ∇, where π^{-1} is the reverse list of π.

The interesting inference rules for α-equivalence are those for abstractions and suspended variables. For abstraction we have two possible cases: $(\approx_\alpha [\mathbf{aa}])$ and $(\approx_\alpha [\mathbf{ab}])$. In the former case, one needs to check whether the abstracted terms are α-equivalent under the same context, and in the latter case, when the abstraction is built with different atoms, one needs to check whether renaming one of the abstracted terms by swapping these different atoms, the α-equivalence with the other abstracted term holds, in addition, the new atom has to be fresh in the abstracted term that is renamed. From the nominal syntax specified in Coq, the proof that `alpha_equiv` (that is, $\approx_\alpha$ of Figure 2) is in fact an equivalence relation was formalised.

3. Formalisation of soundness of the $\approx_\alpha$ relation

This section shortly describes the proofs formalised in Coq about the fact that the relation $\approx_\alpha$ given in Figure 2 is indeed an equivalence relation.

Lemma 1 (Equivariance of Freshness)**.** $\nabla \vdash a \# s$ *iff* $\nabla \vdash \pi \cdot a \# \pi \cdot s$.

Lemma 2 (Freshness preservation under $\approx_\alpha$)**.** $\nabla \vdash a \# s$ *and* $\nabla \vdash s \approx_\alpha t$ *imply* $\nabla \vdash a \# t$.

Lemma 3 (Inversion of permutations over $\approx_\alpha$)**.** $\nabla \vdash \pi \cdot s \approx_\alpha t$ *implies* $\nabla \vdash s \approx_\alpha \pi^{-1} \cdot t$

Lemma 4 (Equivariance of $\approx_\alpha$)**.** $\nabla \vdash s \approx_\alpha t$ *iff* $\nabla \vdash \pi \cdot s \approx_\alpha \pi \cdot t$.

Lemma 5 (Invariance of $\approx_\alpha$ under the action of permutations)**.** $(\forall a \in ds(\pi, \pi'),\ \nabla \vdash a \# t)$ *iff* $\nabla \vdash \pi \cdot t \approx_\alpha \pi' \cdot t$.

Lemmas 1 and 3 to 5 are proved by induction on the structure of s. Lemma 2 is proved by induction on the derivation cases of $\approx_\alpha$. For Lemma 3, Lemma 2 is also applied.

Lemma 6 (Reflexivity of $\approx_\alpha$)**.** $\nabla \vdash t \approx_\alpha t$

Reflexivity of $\approx_\alpha$ is proved by induction on the structure of t.

Lemma 7 (Symmetry of $\approx_\alpha$)**.** *If* $\nabla \vdash s \approx_\alpha t$ *then* $\nabla \vdash t \approx_\alpha s$.

Symmetry of $\approx_\alpha$ is verified through an inductive proof over $\nabla \vdash s \approx_\alpha t$ on the derivation rules of $\approx_\alpha$. The interesting case is given by rule ($\approx_\alpha$ [**ab**]). In this case, $\nabla \vdash [a]u \approx_\alpha [b]v$ whenever $\nabla \vdash u \approx_\alpha (a\,b)\,v$ and $\nabla \vdash a \# v$. By equivariance of freshness (Lemma 1), we obtain $\nabla \vdash b \# (a\,b)\,v$. By induction hypothesis (for short, IH), $\nabla \vdash (a\,b)\,v \approx_\alpha u$ and then $\nabla \vdash b \# u$, by Lemma 2. Finally, by inversion of permutations over $\approx_\alpha$ (Lemma 3), $\nabla \vdash v \approx_\alpha (a\,b)\,u$. This and $\nabla \vdash b \# u$ prove $\nabla \vdash [b]v \approx_\alpha [a]u$.

The proof of transitivity of $\approx_\alpha$ (Lemma 8) is shown in detail, since the formalisation given in [6] uses a weak equivalence relation to deal with the case of abstraction. In this paper, we achieved the transitivity of $\approx_\alpha$ in a direct manner as done in [5], where this equivalence is used as part of a PVS formalisation of nominal unification and the technique is fully described.

Lemma 8 (Transitivity of $\approx_\alpha$)**.** *The relation* $\approx_\alpha$ *is transitive under a given context* ∇*, i.e.,* $\nabla \vdash t_1 \approx_\alpha t_2$ *and* $\nabla \vdash t_2 \approx_\alpha t_3$ *imply* $\nabla \vdash t_1 \approx_\alpha t_3$.

Proof. The proof is by induction on the size of t_1 and case analysis over $\nabla \vdash t_1 \approx_\alpha t_2$ and $\nabla \vdash t_2 \approx_\alpha t_3$. The subsequent steps show the abstraction case, which is the most interesting one due to the asymmetry of rule ($\approx_\alpha$ [**ab**]) (see Figure 2). Consider $t_1 = [a]u$, $t_2 = [b]v$ and $t_3 = [c]w$. So one must analyse the following situations:

- $a = b = c$: thus the result follows by IH;
- $a = b \neq c$: by definition, $\nabla \vdash u \approx_\alpha v$ and $\nabla \vdash v \approx_\alpha (b\,c)\,w$ and $\nabla \vdash b \# w$. By IH, $\nabla \vdash u \approx_\alpha (b\,c)\,w$. As $a = b$, then freshness condition to a is satisfied as well;
- $a \neq b = c$: we have that $\nabla \vdash a \# v$, $\nabla \vdash u \approx_\alpha (a\,c)\,v$ and $\nabla \vdash v \approx_\alpha w$. By Lemma 4, $\nabla \vdash (a\,c)\,v \approx_\alpha (a\,c)\,w$ and, by IH, $\nabla \vdash u \approx_\alpha (a\,c)\,w$. By Lemma 1, $\nabla \vdash c \# (a\,c)\,v$ and $\nabla \vdash c \# (a\,c)\,w$ by Lemma 2. Finally, again by Lemma 1, $\nabla \vdash a \# w$;
- $b \neq a = c$: it is known that $\nabla \vdash u \approx_\alpha (b\,c)\,v$ and $\nabla \vdash v \approx_\alpha (b\,c)\,w$. Then $\nabla \vdash (b\,c)\,v \approx_\alpha w$ by Lemma 3. By IH $\nabla \vdash u \approx_\alpha w$;
- $a \neq b \neq c \neq a$: it is necessary to prove that $\nabla \vdash u \approx_\alpha (a\,c)\,w$ and $\nabla \vdash a \# w$. Let us prove first the freshness condition. by definition of $\approx_\alpha$, $\nabla \vdash a \# v$ and $\nabla \vdash v \approx_\alpha (b\,c)\,w$. By Lemma 2, $\nabla \vdash a \# (b\,c)\,w$ and, by Lemma 1, $\nabla \vdash a \# w$. Now let us prove $\approx_\alpha$: By Lemma 4, $\nabla \vdash (a\,b)\,v \approx_\alpha [(b\,c),(a\,b)] \cdot w$. As $ds([(b\,c),(a\,b)],(a\,c)) = \{a,b\}$ and both atoms are fresh in w, then $\nabla \vdash [(b\,c),(a\,b)] \cdot w \approx_\alpha (a\,c)\,w$ by Lemma 5. Now, applying IH twice, one obtains $\nabla \vdash u \approx_\alpha (a\,c)\,w$.

□

This approach that does not use weak equivalence, reduces considerably the effort necessary to formalise the transitivity of $\approx_\alpha$. The new strategy results in a reduction of 161 proof lines in the formalisation as discussed below.

On one hand, a few auxiliary lemmas were necessary about properties of difference sets and the relations # and $\approx_\alpha$. Among them there are some lemmas that were easily proved in the former formalisation using $\approx_\alpha$-transitivity such as inversion of permutations over $\approx_\alpha$ (Lemma 3). Notice that this lemma is now necessary for proving symmetry and transitivity of $\approx_\alpha$ (see Lemmas 7, 8). Other new auxiliary lemmas specify very simple properties that are now used for the inductive analysis in the proofs of symmetry and transitivity of $\approx_\alpha$, such as:

$ds(\pi, \pi') = \emptyset$ implies

1. $\nabla \vdash \pi \cdot s \approx_\alpha t$ iff $\nabla \vdash \pi' \cdot s \approx_\alpha t$;
2. $\nabla \vdash s \approx_\alpha \pi \cdot t$ iff $\nabla \vdash s \approx_\alpha \pi' \cdot t$; and
3. $\nabla \vdash a \# \pi \cdot s$ iff $\nabla \vdash a \# \pi' \cdot s$.

These lemmas are proved by induction on terms. The same technique is used in the formalisation of Lemma 3. All these results added only 177 proof lines.

On the other hand, all definitions and results about $\sim_\omega$ are no longer needed in the new approach. Statements similar to Lemmas 2 and 4 (freshness preservation and equivariance, respectively) that were proved for the weak equivalence $\sim_\omega$ are not necessary. Also, two auxiliary lemmas that were crucial in the former approach for the proof of transitivity of $\approx_\alpha$ are eliminated, namely: $\nabla \vdash t_1 \approx_\alpha t_2$ and $t_2 \sim_\omega t_3$ implies $\nabla \vdash t_1 \approx_\alpha t_3$; and $\nabla \vdash t_1 \approx_\alpha t_2$ and $\nabla \vdash t_2 \approx_\alpha \pi \cdot t_2$ implies $\nabla \vdash t_1 \approx_\alpha \pi \cdot t_2$. The former property establishes an intermediate transitivity combining $\approx_\alpha$ and $\sim_\omega$. This lemma was used in the proof of the latter auxiliary lemma, as well as in the proof of equivariance, transitivity and symmetry; in all cases used for proving the case of application of the rule $(\approx_\alpha [\mathbf{ab}])$. The latter property had a non trivial formalisation which required as much effort as the former proof of transitivity for $\approx_\alpha$. This lemma was used only in the proof of transitivity, also for proving the case of application of the rule $(\approx_\alpha [\mathbf{ab}])$. Both these auxiliary lemmas were proved by induction on the derivation rules of $\nabla \vdash t_1 \approx_\alpha t_2$. Counting all these lemmas, a total of 338 proof lines were eliminated.

As well as been shorter than the specification using weak equivalence, the current approach has the advantage that the proof of symmetry (Lemma 7) is now independent of the proof of transitivity (Lemma 8). In the previous approach, symmetry was obtained as consequence of transitivity. Despite this, it is important to stress that in both approaches the proofs of symmetry were done by induction on the derivation rules, while the proofs of transitivity by induction on the size of terms. The number of proof lines in the formalisations of the lemmas of symmetry and transitivity are almost the same in both approaches.

To check α-equivalence modulo A, C and AC, denoted $\approx_{\{A,C,AC\}}$, one uses soundness of $\approx_\alpha$. Thus, one could adopt any approach for checking $\approx_\alpha$ and adapt it to check $\approx_{\{A,C,AC\}}$. More specifically, we specify an inductive relation $\texttt{equiv}(S)$, where S is a set of indices, each one associated with a different equational theory. In particular, the relation $\texttt{equiv}(\emptyset)$ excludes from the specification of `equiv`, all specialised inference rules for any equational theory. The relation $\texttt{equiv}(\emptyset)$ is formally proved to be equivalent to the relation $\approx_\alpha$:

$\nabla \vdash t \approx_\alpha t' \Leftrightarrow \texttt{equiv}(\emptyset)(\nabla, t, t')$.

4. Formalising soundness of $\approx_{\{A,C,AC\}}$, $\approx_{\alpha,A}$, $\approx_{\alpha,C}$ and $\approx_{\alpha,AC}$

The generic relation $\texttt{equiv}(S)$ mentioned at the end of Sec. 3, will consider A, C and AC function symbols if $0, 1$ or $2 \in S$, respectively. Namely, $\texttt{equiv}(\{0\})$, $\texttt{equiv}(\{1\})$,$\texttt{equiv}(\{2\})$ and $\texttt{equiv}(\{0,1,2\})$ choose the specialised inductive rules in the definition of equiv for the relation $\approx_\alpha$ modulo A, AC and A combined with AC function symbols, respectively. In this way one builds the relations $\approx_{\alpha,A}$, $\approx_{\alpha,C}$, $\approx_{\alpha,AC}$ and $\approx_{\{A,C,AC\}}$. For simplicity, instead 0, 1 and 2 we will use A, C and AC in the sequel.

4.1. Operations over tuples

The inductive rules for A and AC operators in the definition of the relation $\approx_{\{A,C,AC\}}$ use three auxiliary operators that deal with arguments of function symbols. Arguments of a function symbol f are terms or tuples built using the constructor for pairs and the arguments of terms headed by the same function symbol f. These operators, specified as in Fig. 3, extract the relevant information of the arguments to which a(n A or AC) symbol f_n^E is applied and specify the *length or number of arguments*, $\|t\|_{f_n^E} := \mathsf{TPlength}\, t\, E\, n$, and the *selection* and *deletion of the i^{th} argument*, respectively, $t_{(i)_{f_n^E}} := \mathsf{TPith}\, i\, t\, E\, n$ and $t_{[\star i]_{f_n^E}} := \mathsf{TPithdel}\, i\, t\, E\, n$.

To simplify notation, the scripts of f will be omitted in these operators when clear from the context. The behaviour of these operators is illustrated below.

Example 2. *For the number of arguments.*

1. $\|f\langle\,\rangle\|_f = \|\langle\,\rangle\|_f = 1$;
2. $\|f\,\langle \overline{a}, \overline{b}\rangle\|_f = \|\langle \overline{a}, \overline{b}\rangle\|_f = 2$, *but* $\|g\,\langle \overline{a}, \overline{b}\rangle\|_f = 1$;
3. $\|f\,\langle [a](\pi \cdot X), f\,\langle \overline{b}, g\,\langle \overline{a}, f\,\langle \overline{a}, \overline{b}\rangle\rangle\rangle\|_f =$
   $\|[a](\pi \cdot X)\|_f + \|\overline{b}\|_f + \|g\,\langle \overline{a}, f\,\langle \overline{a}, \overline{b}\rangle\rangle\|_f = 3$.

Example 3. *For the selection of the i^{th} argument.*

1. $t_{(0)_f} = t_{(1)_f}$ *and, if* $i > \|t\|_f$ *then* $t_{(i)_f} = t_{(\|t\|_f)_f}$;
2. *If* $\|t\|_f = 1$ *and* t *is not headed by* f *then* $t_{(1)_f} = t$, *but also* $(f\, f\, t)_{(1)_f} = t$;
3. $(f\,\langle [a](\pi \cdot X), f\,\langle \overline{b}, g\,\langle \overline{a}, f\,\langle \overline{a}, \overline{b}\rangle\rangle\rangle\rangle)_{(3)_f} = (f\,\langle \overline{b}, g\,\langle \overline{a}, f\,\langle \overline{a}, \overline{b}\rangle\rangle\rangle)_{(2)_f} =$
   $(g\,\langle \overline{a}, f\,\langle \overline{a}, \overline{b}\rangle\rangle)_{(1)_f} = g\,\langle \overline{a}, f\,\langle \overline{a}, \overline{b}\rangle\rangle$.

Figure 3: Specification of operators for the length of the tuple or arguments, selection and deletion of the i^{th} argument regarding the function symbol f

Example 4. *For the deletion of the i^{th} argument.*

1. $t_{[\star 0]_f} = t_{[\star 1]_f}$ *and if* $i > \|t\|_f$ *then* $t_{[\star i]_f} = t_{[\star \|t\|_f]_f}$;
2. *If* $\|t\|_f = 1$ *then* $t_{[\star 1]_f} = \langle\,\rangle$;
3. $(f\,\langle [a](\pi \cdot X), f\,\langle \overline{b}, g\,\langle \overline{a}, f\,\langle \overline{a}, \overline{b}\rangle\rangle\rangle\rangle)_{[\star 2]_f} =$
   $f\,\langle [a](\pi \cdot X), (f\,\langle \overline{b}, g\,\langle \overline{a}, f\,\langle \overline{a}, \overline{b}\rangle\rangle\rangle)_{[\star 1]_f}\rangle = f\,\langle [a](\pi \cdot X), f\,(g\,\langle \overline{a}, f\,\langle \overline{a}, \overline{b}\rangle\rangle)\rangle$.

It should be clear to the reader that the specification follows the lines of nominal syntax in which function symbols have no fixed arity. Thus for any A or AC symbol it should be interpreted apart what means its application to the unit ($\langle\rangle$) and to a single argument, for instance, with the usual interpretation for operator symbols, $\wedge\langle\rangle$, $\vee\langle\rangle$, $+\langle\rangle$ and $\times\langle\rangle$ might be specified as "false", "true", 0 and 1, respectively.

Using these operators one obtains two advantages that allow to specify properties directly over the nominal syntax: first, it is neither necessary an additional data structure to express associativity (e.g. lists, sequences, arrays) nor an operator for *flattening* terms; second, the grammar adopted, and the behaviour of the rules allow manipulation of arbitrary combinations of different function symbols with different equational properties, in a natural way. Thus, function symbols with different equational properties might occur in a term being only necessary the application of specialised inference rules that deal with their equational properties. This simplifies the treatment of α-equivalence modulo A, C and AC, and other equational theories.

In Table 1 a few formalised results are listed, from a much longer list of formalised lemmas related with these operators. These results will be referenced in the description of the lemmas related with E-equivalence and for brevity they are presented free of universal quantifiers.

Table 1: Basic properties of the operators over terms: $\|\_\|_f$, $\_(\_)_f$ and $\_[\star\_]_f$

$\|t\| \geq 1,\ t_{(0)} = t_{(1)},\ t_{[\star 0]} = t_{[\star 1]}$	$i \geq \|t\| \Rightarrow t_{(i)} = t_{(\|t\|)},\ t_{[\star i]} = t_{[\star \|t\|]}$
$\|t\| = 1 \Rightarrow t_{[\star i]} = \langle\,\rangle$	$\|t\| \neq 1 \Rightarrow \|t_{[\star i]}\| = \|t\| - 1$
$0 < i < j$ or $0 < i < \|t\| \Rightarrow (t_{[\star j]})_{(i)} = t_{(i)}$	$0 < i < j \leq \|t\| \Rightarrow (t_{[\star j]})_{[\star i]} = (t_{[\star i]})_{[\star (j-1)]}$
$0 < i < \|t\|,\ i \geq j \Rightarrow (t_{[\star j]})_{(i)} = t_{(i+1)},\ (t_{[\star j]})_{[\star i]} = (t_{[\star (i+1)]})_{[\star j]}$	

4.2. Extension of the $\approx_\alpha$-rules

New rules ($\approx_\alpha$ **A**), ($\approx_\alpha$ **C**), and ($\approx_\alpha$ **AC**) for associativity, commutativity and associativity-commutativity are introduced. These rules will be combined with those from Fig. 2 for $\approx_\alpha$, with the following modification: ($\approx_\alpha$ **app**) will be replaced by ($\approx_\alpha$ $\overline{\textbf{app}}$) and applies whenever the function symbol f_k^E applied to s is such that $E \notin S$ or $E = C \in S$ and s is not a pair. Otherwise, when $E = A, C$ or AC and $E \in S$, rules ($\approx_\alpha$ **A**), ($\approx_\alpha$ **C**) or ($\approx_\alpha$ **AC**) apply. Therefore, in the case f is not an A, C or AC function symbol or $A, C, AC \notin S$, the behaviour of ($\approx_\alpha$ $\overline{\textbf{app}}$) and ($\approx_\alpha$ **app**) would be exactly the same. These rules define an extended calculus for *general* α-equivalence modulo A, C and AC ([20]), denoted by the relation $\approx_{\{A,C,AC\}}$ (specified as `equiv({0,1,2})`). Other equational theories might be included similarly. Below, $\nabla \vdash s \approx_{\{A,C,AC\}} t$ denotes that s and t are α-equivalent modulo A, C and AC under the context ∇.

$$\frac{\nabla \vdash s \approx_{\{A,C,AC\}} t}{\nabla \vdash f_k^E s \approx_{\{A,C,AC\}} f_k^E t} \quad \begin{array}{l} E \notin S \text{ or} \\ E = C \text{ and } s \text{ is not a pair} \end{array} \quad (\approx_\alpha \overline{\textbf{app}})$$

Figure 4: ($\approx_\alpha$ $\overline{\textbf{app}}$)-rule for $\approx_{\{A,C,AC\}}$

$$\frac{\begin{array}{l} \nabla \vdash (f_k^A\, s)_{(\mathbf{1})_{f_k^A}} \approx_{\{A,C,AC\}} (f_k^A\, t)_{(\mathbf{1})_{f_k^A}}, \\ \nabla \vdash (f_k^A\, s)_{[\star\mathbf{1}]_{f_k^A}} \approx_{\{A,C,AC\}} (f_k^A\, t)_{[\star\mathbf{1}]_{f_k^A}} \end{array}}{\nabla \vdash f_k^A\, s \approx_{\{A,C,AC\}} f_k^A\, t} \quad (\approx_\alpha \textbf{A})$$

Figure 5: ($\approx_\alpha$ **A**)-rule for A function symbols

Rule ($\approx_\alpha$ **A**) applies when the terms compared are headed by the same A function symbol and $A \in S$. It verifies recursively if the first arguments on the left (*lhs*) and right-hand sides (*rhs*) are related by $\approx_{\{A,C,AC\}}$ as well as the result of applying the root function symbol to the respective tuples without the first argument.

Rule ($\approx_\alpha$ **C**) has two possibilities of application: for $i = 0$ (resp. $i = 1$) one must have $\nabla \vdash s_0 \approx_{\{A,C,AC\}} t_0$ and $\nabla \vdash s_1 \approx_{\{A,C,AC\}} t_1$ (resp. $\nabla \vdash s_0 \approx_{\{A,C,AC\}} t_1$ and $\nabla \vdash s_1 \approx_{\{A,C,AC\}} t_0$). The case where f_K^C is applied to a term different of a pair is considered in the ($\approx_\alpha$ $\overline{\textbf{app}}$)-rule.

$$\frac{\nabla \vdash s_0 \approx_{\{A,C,AC\}} t_i,\ \nabla \vdash s_1 \approx_{\{A,C,AC\}} t_{(i+1)\,mod\,2}}{\nabla \vdash f_k^C\,\langle s_0, s_1\rangle \approx_{\{A,C,AC\}} f_k^C\,\langle t_0, t_1\rangle}\ i = 0,1\ (\approx_\alpha \mathbf{C})$$

Figure 6: $(\approx_\alpha \mathbf{C})$-rule for C function symbols

$$\frac{\begin{array}{l}\nabla \vdash (f_k^{AC}\,s)_{(\mathbf{1})_{f_k^{AC}}} \approx_{\{A,C,AC\}} (f_k^{AC}\,t)_{(\mathbf{i})_{f_k^{AC}}},\\ \nabla \vdash (f_k^{AC}\,s)_{[\star\mathbf{1}]_{f_k^{AC}}} \approx_{\{A,C,AC\}} (f_k^{AC}\,t)_{[\star\mathbf{i}]_{f_k^{AC}}}\end{array}}{\nabla \vdash f_k^{AC}\,s \approx_{\{A,C,AC\}} f_k^{AC}\,t}\ AC \in S\ (\approx_\alpha \mathbf{AC})$$

Figure 7: $(\approx_\alpha \mathbf{AC})$-rule for AC function symbols

Rule $(\approx_\alpha \mathbf{AC})$ behaves similarly to rule $(\approx_\alpha \mathbf{A})$: the fundamental difference is that the first argument on the *lhs* can be compared modulo $\approx_{\{A,C,AC\}}$ with any arbitrary argument on the *rhs*. If there exists such argument, say the i^{th}, it remains to check that the terms obtained applying the function symbol to the tuples deleting the first and the i^{th} arguments to the right and to the left are related by $\approx_{\{A,C,AC\}}$.

Example 5. $\nabla \vdash f\,\langle t_1, g^{AC}\,\langle t_2, g^{AC}\langle t_3, t_4\rangle\rangle\rangle \approx_{\{A,C,AC\}} f\,\langle t_1, g^{AC}\,\langle\langle t_4, t_3\rangle, t_2\rangle\rangle$, *where g is AC, f is a function symbol that allows only α-equivalence and $AC \in S$.*

4.3. Checking $\approx_{\{A,C,AC\}}$, $\approx_{\alpha,A}$, $\approx_{\alpha,C}$ and $\approx_{\alpha,AC}$

The following steps were performed in order to check that $\approx_{\{A,C,AC\}}$ is indeed an equivalence relation. After proving an intermediate transitivity lemma for $\approx_{\{A,C,AC\}}$ (Lemma 9), one proves *freshness preservation* and *equivariance* (Lemmas 10, 11) of $\approx_{\{A,C,AC\}}$ and then, transitivity before symmetry (Lemmas 14 and 15). By using the parameter set S on the $\texttt{equiv}(S)$ relation and renaming superscripts of function symbols, one obtains as corollary of the soundness $\approx_{\{A,C,AC\}}$ the soundness of $\approx_{\alpha,A}$, $\approx_{\alpha,C}$ and $\approx_{\alpha,AC}$.

In addition to preservation of freshness and equivariance, the intermediate transitivity lemma (Lemma 9) is relevant to guarantee some key properties on swappings and permutations acting over $\approx_{\{A,C,AC\}}$-related terms as for instance, $\nabla \vdash t \approx_{\{A,C,AC\}} (a\,a')\,t' \Rightarrow \nabla \vdash (a'\,a)\,t \approx_{\{A,C,AC\}} t'$.

Lemma 9 (Intermediate transitivity for $\approx_{\{A,C,AC\}}$ with $\approx_\alpha$)**.** *If $\nabla \vdash s \approx_{\{A,C,AC\}} t$ and $\nabla \vdash t \approx_\alpha u$ then $\nabla \vdash s \approx_{\{A,C,AC\}} u$.*

The formalisation is obtained as follows: after generalisation of u, induction is applied on deduction rules of $\approx_{\{A,C,AC\}}$ for $\nabla \vdash s \approx_{\{A,C,AC\}} t$. In some cases it is required inversion of $\nabla \vdash t \approx_{\{A,C,AC\}} u$; for instance, in the case in which one has $t = \langle t_1, t_2 \rangle$, inversion is applied to obtain that $u = \langle u_1, u_2 \rangle$ with $\nabla \vdash t_1 \approx_{\{A,C,AC\}} u_1$ and $\nabla \vdash t_2 \approx_{\{A,C,AC\}} u_2$, according to the inference rule $(\approx_\alpha \mathbf{pair})$.

Lemma 10 (Freshness preservation under $\approx_{\{A,C,AC\}}$)**.** *If* $\nabla \vdash a \# s$ *and* $\nabla \vdash s \approx_{\{A,C,AC\}} t$ *then* $\nabla \vdash a \# t$.

The proof is by induction on $\approx_{\{A,C,AC\}}$, using some technical results about the freshness relation for dealing with cases related with rules $(\approx_\alpha [\mathbf{aa}])$ and $(\approx_\alpha [\mathbf{ab}])$ for the case in which s and t are abstractions.

Lemma 11 (Equivariance of $\approx_{\{A,C,AC\}}$)**.** *If* $\nabla \vdash s \approx_{\{A,C,AC\}} t$ *then* $\nabla \vdash \pi \cdot s \approx_{\{A,C,AC\}} \pi \cdot t$.

Equivariance follows by induction in the inference rules of $\approx_{\{A,C,AC\}}$. For the case of abstractions, specifically for the case of the rule $(\approx_\alpha [\mathbf{ab}])$, Lemma 9 is required; indeed, when one has $\nabla \vdash [a]s' \approx_{\{A,C,AC\}} [b]t'$, initially it is necessary to prove that $\nabla \vdash \pi \cdot s' \approx_{\{A,C,AC\}} \pi \cdot ((a\ b) \cdot t')$ and $\nabla \vdash \pi \cdot ((a\ b) \cdot t') \approx_\alpha (\pi \cdot a\ \ \pi \cdot b) \cdot (\pi \cdot t')$ and then apply that lemma to obtain $\nabla \vdash \pi \cdot s' \approx_{\{A,C,AC\}} (\pi \cdot a\ \ \pi \cdot b) \cdot (\pi \cdot t')$.

Lemma 12 (Reflexivity of $\approx_{\{A,C,AC\}}$)**.** $\nabla \vdash t \approx_{\{A,C,AC\}} t$.

Reflexivity is easily proved by induction on t. The next lemma generalises the way in which arguments used in the rule $(\approx_\alpha \mathbf{AC})$ are combined.

Lemma 13 (Combination of AC arguments)**.** *If* $\nabla \vdash t \approx_{\{A,C,AC\}} t'$ *then* $\forall_{(0<i\leq \|t\|_f)} \exists_{(0<j\leq \|t\|_f)} \nabla \vdash t_{(i)_f} \approx_{\{A,C,AC\}} t'_{(j)_f}$ *and* $\nabla \vdash t_{[\star i]_f} \approx_{\{A,C,AC\}} t'_{[\star j]_f}$.

The proof is by induction on $\|t\|_f$ using simple auxiliary lemmas and properties of the operators $\|t\|_f, t_{(i)_f}$ and $t_{[\star i]_f}$. We explain how the proof is obtained for the particular case for $i = 1$: $\nabla \vdash t \approx_{\{A,C,AC\}} t' \Rightarrow \exists_{(0<j\leq \|t'\|_f)}, \nabla \vdash t_{(1)_f} \approx_{\{A,C,AC\}} t'_{(j)_f} \wedge \nabla \vdash t_{[\star 1]_f} \approx_{\{A,C,AC\}} t'_{[\star j]}$. The complicated case happens when $\|t\|_f > 2$: after applying the auxiliary lemma for terms $f\, t$ and $f\, t'$ one obtains for some valid i_0, $\nabla \vdash t_{(1)_f} \approx_{\{A,C,AC\}} t'_{(i_0)_f}$ and $\nabla \vdash f\, t_{[\star 1]_f} \approx_{\{A,C,AC\}} f\, t'_{[\star i_0]_f}$. Notice that if $i = 1$, the result follows trivially. For $i > 1$, induction applies for the terms $t_0 = f\, t_{[\star 1]_f}$

and $t'_0 = f\, t'_{[\star i_0]_f}$ with argument $i_1 = i - 1$. Notice that the IH is given as $\forall_{(\|t_0\|_f < \|t\|_f,\, t'_0,\, 0<i_1\leq\|t_0\|_f)} \exists j_1, \nabla \vdash t_{0(i_1)_f} \approx_{\{A,C,AC\}} t'_{0(j_1)_f}$ and $\nabla \vdash t_{0[\star i_1]_f} \approx_{\{A,C,AC\}} t'_{0[\star j_1]_f}$. Then, applying IH, a witness j is obtained such that, with the pre-conditions: $\|f\, t_{[\star 1]_f}\|_f < \|t\|_f$ and $\nabla \vdash f\, t_{[\star 1]_f} \approx_{\{A,C,AC\}} f\, t'_{[\star i_0]_f}$, one obtains $\nabla \vdash f\, t_{(i)_f} \approx_{\{A,C,AC\}} f\, t'_{(j)_f}$ and $\nabla \vdash f\, t_{[\star(i)]_f} \approx_{\{A,C,AC\}} f\, t'_{[\star j]_f}$. The first pre-condition is solved by an application of the definition of $\|\_\|$ and an auxiliary lemma for the operators $\|t\|_f$ and $t_{[\star i]_f}$. The second is exactly the assumption. Then one just needs to consider two cases: $i_0 \leq j_1$ or $i_0 > j_1$. One instantiates j respectively as $j_1 + 1$ or j_1 and concludes using properties of the operators $\|t\|_f, t_{(i)_f}$ and $t_{[\star i]_f}$.

Lemma 14 (Transitivity of $\approx_{\{A,C,AC\}}$)**.** *If* $\nabla \vdash t_1 \approx_{\{A,C,AC\}} t_2$ *and* $\nabla \vdash t_2 \approx_{\{A,C,AC\}} t_3$ *then* $\nabla \vdash t_1 \approx_{\{A,C,AC\}} t_3$.

The formalisation is by induction on the size of the term t_1. The terms t_2 and t_3 are generalised, and inversions from the equational inference rules are applied to both $\nabla \vdash t_1 \approx_{\{A,C,AC\}} t_2$ and $\nabla \vdash t_2 \approx_{\{A,C,AC\}} t_3$. The difficult cases are those of rules ($\approx_\alpha$ [**ab**]) and ($\approx_\alpha$ **A**) or ($\approx_\alpha$ **AC**). For ($\approx_\alpha$ [**ab**]), an interesting subcase is when $a \neq a' \neq a'_0 \neq a$: the premisses are $\nabla \vdash t \approx_{\{A,C,AC\}} (a\, a')\, t' \;\wedge\; \nabla \vdash a \# t'$ and $\nabla \vdash t' \approx_{\{A,C,AC\}} (a'\, a'_0)\, t'_0 \;\wedge\; \nabla \vdash a'_0 \# t'_0$, the IH is given as $\forall_{(s_1,s_2,s_3)}, |s_1| < |t| \wedge (\nabla \vdash s_1 \approx_{\{A,C,AC\}} s_2 \wedge \nabla \vdash s_2 \approx_{\{A,C,AC\}} s_3) \Rightarrow \nabla \vdash s_1 \approx_{\{A,C,AC\}} s_3$, and one should conclude that $\nabla \vdash [a]t \approx_{\{A,C,AC\}} [a'_0]t'_0$. Applying ($\approx_\alpha$ [**ab**]) it remains to prove that $\nabla \vdash a \# t'_0$ and $\nabla \vdash t \approx_{\{A,C,AC\}} (a\, a'_0)\, t'_0$. The former is obtained by freshness preservation, and the latter by IH with application of Lemma 9, equivariance and freshness preservation.

In the case of rules ($\approx_\alpha$ **A**) or ($\approx_\alpha$ **AC**), the following proof context is reached at some point of the formalisation, where for the case of ($\approx_\alpha$ **A**), the indices i and i_0 are equal to 1: the premisses are $\nabla \vdash t_{(1)_{f_k^E}} \approx_{\{A,C,AC\}} t'_{(i)_{f_k^E}} \wedge \nabla \vdash f_k^E\, t_{[\star 1]_{f_k^E}} \approx_{\{A,C,AC\}} f_k^E\, t'_{[\star i]_{f_k^E}}$, and $\nabla \vdash t'_{(1)_{f_k^E}} \approx_{\{A,C,AC\}} t'_{0(i_0)_{f_k^E}} \wedge \nabla \vdash f_k^E\, t'_{[\star 1]_{f_k^E}} \approx_{\{A,C,AC\}} f_k^E\, t'_{0[\star i_0]_{f_k^E}}$, the IH is given by $\forall_{(s_1,s_2,s_3)}, |s_1| < |f_k^E\, t| \wedge (\nabla \vdash s_1 \approx_{\{A,C,AC\}} s_2 \wedge \nabla \vdash s_2 \approx_{\{A,C,AC\}} s_3) \Rightarrow \nabla \vdash s_1 \approx_{\{A,C,AC\}} s_3$, and one should conclude that $\nabla \vdash f_k^E\, t \approx_{\{A,C,AC\}} f_k^E\, t'_0$. Applying ($\approx_\alpha$ **A**) and the IH one concludes easily for the case in which $E = A$. When $E = AC$ one uses the Lemma 13 and the second premise above, obtaining a third premise: $\exists i_1, \nabla \vdash t'_{(i)_{f_k^E}} \approx_{\{A,C,AC\}} t'_{0(i_1)_{f_k^E}} \wedge \nabla \vdash t'_{[\star i]_{f_k^E}} \approx_{\{A,C,AC\}} t'_{0[\star i_1]_{f_k^E}}$. Then, applying the ($\approx_\alpha$ **AC**) rule instantiated with i_1. The resulting subgoals are $\nabla \vdash t_{(1)_{f_k^E}} \approx_{\{A,C,AC\}} t'_{0(i_1)_{f_k^E}}$ and $\nabla \vdash f_k^E\, t_{[\star 1]_{f_k^E}} \approx_{\{A,C,AC\}} f_k^E\, t'_{0[\star i_1]_{f_k^E}}$, and from

the first and third premises above, both subgoals are solved by application of IH.

Lemma 15 (Symmetry of $\approx_{\{A,C,AC\}}$)**.** *If* $\nabla \vdash t \approx_{\{A,C,AC\}} t'$ *then* $\nabla \vdash t' \approx_{\{A,C,AC\}} t$.

Symmetry is easily formalised by induction on $\approx_{\{A,C,AC\}}$ applying lemmas 9, 12 and 14, freshness preservation and equivariance.

In particular, the use of the Lemma 14 is crucial: in the $(\approx_\alpha [\mathbf{ab}])$ case one should poof that $\nabla \vdash [b]t' \approx_{\{A,C,AC\}} [a]t$ having as hypotheses $\nabla \vdash t \approx_{\{A,C,AC\}} (a\,b)\,t'$ and $\nabla \vdash a \# t'$, with IH $\nabla \vdash (a\,b)\,t' \approx_{\{A,C,AC\}} t$. Then, Lemma 14 is applied twice instantiating t_2 as $(a,b)\,t$ and as $(a\,b)\,(a\,b)\,t'$, that allows the use of Lemmas 9 (with properties of $\approx_\alpha$) and equivariance to conclude.

To check $\approx_{\alpha,A}$, $\approx_{\alpha,C}$ and $\approx_{\alpha,AC}$ one uses the following corollary. Remember that $\approx_{\alpha,A}$, $\approx_{\alpha,C}$, $\approx_{\alpha,AC}$ and $\approx_{\{A,C,AC\}}$ are specified as $\texttt{equiv}(\{0\})$, $\texttt{equiv}(\{1\})$, $\texttt{equiv}(\{2\})$ and $\texttt{equiv}(\{0,1,2\})$.

Corollary 1. *For* $S \subseteq \{0,1,2\}$, $\texttt{equiv}(S)$ *is also an equivalence relation.*

The formalisation is obtained by the manipulation of the superscritps in $S^{-1} = \{0,1,2\} - S$. For a general equivalence problem $\texttt{equiv}(S)(\nabla, t_1, t_2)$, one replaces all superscripts of the operators in the terms t_1 and t_2 inside the set S^{-1} for new ones that neither belong to $\{0,1,2\}$ nor occur in t_1 and t_2 obtaining respectivelly t_1' and t_2'. Then, by induction on the inference rules for $\texttt{equiv}$, one easily proves that $\texttt{equiv}(S)(\nabla, t_1, t_2) \Leftrightarrow \texttt{equiv}(S)(\nabla, t_1', t_2') \Leftrightarrow \texttt{equiv}(\{0,1,2\})(\nabla, t_1', t_2')$. Thus, using that $\texttt{equiv}(\{0,1,2\})$ is an equivalence relation one concludes.

5. Upper bounds for general $\approx_{\alpha,A}$, $\approx_{\alpha,C}$, $\approx_{\alpha,AC}$, $\approx_{\{A,C,AC\}}$ problems

This section is concerned with the problem of checking the validity of α-equivalence constraints in the presence of A, C and AC function symbols, by applying simplification rules.

For example, using the simplification rules given in [7], a constraint of the form $[a]X \approx_\alpha [b]X$ reduces to the set of constraints $a \# X$, $b \# X$; therefore, $a \# X, b \# X \vdash [a]X \approx_\alpha [b]X$. Similarly, assuming $+$ is an AC function symbol, the equality $\nabla \vdash +\langle s, +\langle t, [a]X\rangle\rangle \approx_{\alpha,AC} +\langle +\langle [b]X, s\rangle, t\rangle$ holds whenever the freshness constraints $a \# X$, $b \# X$ belong to ∇. Equational problems will be written as pairs $\langle \nabla, P\rangle$, where ∇ is a set of freshness constraints and P a set of equations. For simplicity, when no confusion arises brackets will be omitted.

5.1. A naive implementation

An algorithm for checking a problem $\langle \nabla, P \rangle$ modulo A/C/AC is defined by the mutually recursive functions `Check` and $\texttt{Check}_{\texttt{AC}}$ given in Algorithms 1 and 2. This algorithm simply distinguishes the cases that should be considered to deal with A/C/AC function symbols. The algorithm was implemented (in OCaml) with the sole objective of computationally deciding equational queries. To obtain efficient algorithms, the techniques described in the next subsection should be used (see the complexity analysis given in next section, Theorem 1).

Example 6. *Assuming* $\nabla = \{a \# X, b \# X\}$ *and using the algorithm, it follows that*

$$\begin{aligned}
&\nabla, \{[a]g\langle \bar{a}, X\rangle \approx [b]g\langle \bar{b}, X\rangle\} \Longrightarrow_{Line\,12} \nabla, \{g\langle \bar{a}, X\rangle \approx (a\,b)\cdot g\langle \bar{b}, X\rangle\} \\
&= \nabla, \{g\langle \bar{a}, X\rangle \approx g\langle \bar{a}, (a\,b).X\rangle\} \Longrightarrow_{Line\,34} \nabla, \{\langle \bar{a}, X\rangle \approx \langle \bar{a}, (a\,b)X\rangle\} \\
&\Longrightarrow_{Line\,8} \nabla, \{\bar{a} \approx \bar{a}, X \approx (a\,b).X\} \Longrightarrow_{Line\,6,16,2} \nabla, \emptyset \Longrightarrow \top
\end{aligned}$$

Example 7. *Consider the problem* $\langle \emptyset, \{f_k^A\langle \bar{a}, \langle \bar{b}, [a]\bar{a}\rangle\rangle \approx f_k^A\langle\langle \bar{a}, \bar{b}\rangle, [b]\bar{b}\rangle\}\rangle$.

$$\begin{aligned}
&\emptyset, \{f_k^A\langle \bar{a}, \langle \bar{b}, [a]\bar{a}\rangle\rangle \approx f_k^A\langle\langle \bar{a}, \bar{b}\rangle, [b]\bar{b}\rangle\} \\
&\Longrightarrow_{Line\,19,24} \emptyset, \{f_k^A\langle \bar{b}, [a]\bar{a}\rangle \approx f_k^A\langle \bar{b}, [b]\bar{b}\rangle\}, \quad \textit{since } \texttt{Check}(\emptyset, \bar{a} \approx \bar{a}) \textit{ (Line 23)} \\
&\Longrightarrow_{Line\,19,24} \emptyset, \{f_k^A[a]\bar{a} \approx f_k^A[b]\bar{b}\}, \quad \textit{since } \texttt{Check}(\emptyset, \bar{b} \approx \bar{b}) \textit{ (Line 23)} \\
&\Longrightarrow_{Line\,19,24} \emptyset, \emptyset, \quad \textit{since } \texttt{Check}([a]\bar{a} \approx [b]\bar{b}) \textit{ (Line 23)} \\
&\Longrightarrow_{Line\,2} \top
\end{aligned}$$

Example 8. *Consider the problem* $\langle \emptyset, \{f_k^C\langle \bar{b}, [a]\bar{a}\rangle \approx f_k^C\langle [b]\bar{b}, \bar{b}\rangle\}\rangle$.

$$\begin{aligned}
&\emptyset, \{f_k^C\langle \bar{b}, [a]\bar{a}\rangle \approx f_k^C\langle [b]\bar{b}, \bar{b}\rangle\} \\
&\Longrightarrow_{Line\,33} \emptyset, \{\bar{b} \approx \bar{b},\ [a]\bar{a} \approx [b]\bar{b}\}, \\
&\qquad\qquad \textit{since } \texttt{Check}(\emptyset, \{\bar{b} \approx [b]\bar{b},\ [a]\bar{a} \approx \bar{b}\}) = \bot \textit{ (L. 31)} \\
&\Longrightarrow_{Line\,6} \emptyset, \{[a]\bar{a} \approx [b]\bar{b}\} \Longrightarrow_{Line\,10,12,2} \top
\end{aligned}$$

Algorithm 2 deals with the case of equations headed by AC-function symbols. The call $\texttt{Check}_{\texttt{AC}}(\nabla, f_k^{AC}s' \approx f_k^{AC}t', 1)$ (in line 38 of Algorithm 1) will start to check equality of the first argument on the *lhs* of the equation with the first, second, third, etc of the *rhs* until this check succeeds and will then recursively check equality of the whole term obtained by eliminating

$\Longrightarrow_{Line\,5,2,\ Alg.1} \top$

Note that the proposed algorithm can check validity of α-equivalence constraints modulo A and/or C and/or AC ($\approx_{\{A,C,AC\}}$) with multiple occurrences of function symbols, some that might be A and some C and some other AC, all at once. This is due to the fact that there are no interactions between A, C, and AC symbols since distributive properties are not considered.

Experiments were performed with this algorithm, over an iMAC server with 16GB of RAM and with a processor Intel Xeon CPU, model W3530 2.80GHz, providing randomly recursively generated ground equational problems as

inputs. Terms were generated using only tuples with arguments associated to the right as arguments for A and AC function symbols. Also, subterms headed by an associative function symbol, say either f_k^A or f_k^{AC}, do not have arguments headed by the same function symbol. For example, $f_0^A\langle \bar{a}, \langle \bar{b}, \langle \bar{c}, \langle \bar{d}, \bar{e}\rangle\rangle\rangle\rangle$ and $f_0^{AC}\langle f_0^A\langle \bar{a}, \bar{b}\rangle, f_4^A\langle \bar{c}, f_0^{AC}\langle \bar{d}, \bar{e}\rangle\rangle\rangle$ are in this class of terms.

Although terms generated in this manner mitigate the manipulation of arguments of associative operators, it should be stressed that in order to have an efficient solution to deal with associative operators, data structures with random access, such as arrays, should be used to flatten the nominal terms. Also, having only ground terms mitigates the negative effects of inefficient procedures for dealing with permutation operations, such as queries about their support, inversion and composition, which are used in the naive algorithm for application of rule ($\approx_\alpha$ **var**).

The number of different syntactic, A, C and AC symbols were restricted to ten (each class), and atoms were chosen among a set of ten thousand. In the recursive generation of an equational problem, when abstractions are created as subterms for the left and right-hand sides of an equation different atoms are used, but collisions might arise if the same atom is used in later stages of the generation. In this case, to guarantee that the problem has positive answer, the body of the abstraction is generated without occurrences of the colliding atom(s).

Four different sets of input problems were generated. The first only uses syntactic function symbols; the second uses also A symbols; the third uses, in addition, C symbols; and, the fourth permits all four kinds of symbols. For each set, problems with positive answer of sizes from 100 to 5000, with intervals of length 100, were generated; for each size fifty different problems were generated. Time performance of the experiments are given respectively in Figures 8, 9, 10 and 11. These figures include also the polynomial regression computed using the linear least-square method generated using the Python library NumPy.

As expected, from the required uniformity of known worst case inputs, which even in the syntactic case will result in exponential running time, in all cases it could be observed that only a few isolated cases present running time much higher than the regression curve. The syntactic case (Figure 8) shows a linear behaviour; adding A- and C-function symbols (Figures 9 and 10) increases the running time, but the behaviour is very similar. This could be explained since the bottleneck of the naive algorithm resides in the inefficient manipulation of permutation operations as well as inefficient data

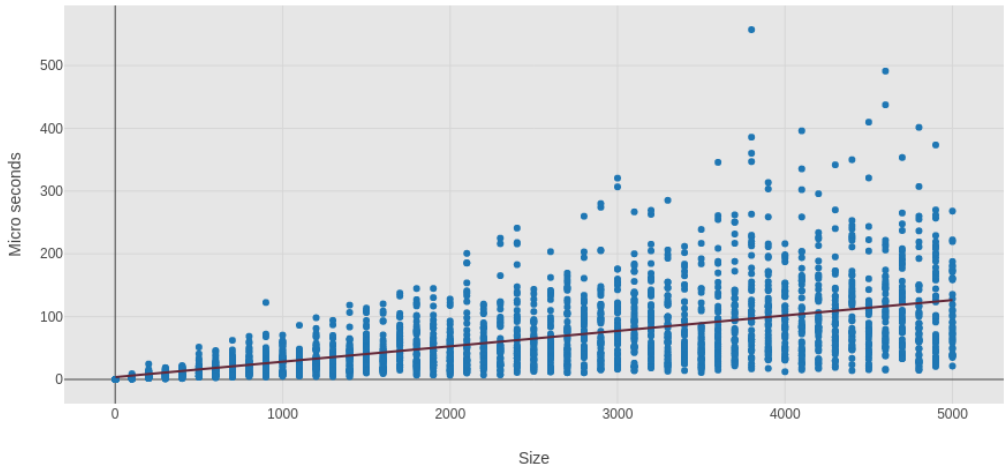

Figure 8: Tests with only abstractions and syntactic function symbols

structure for the representation of terms mitigating in this way the effect of commutativity analysis over problems randomly generated in the explained manner. Substantial additional costs arise if AC-symbols are included (Figure 11), indeed one moves from hundredths of seconds to seconds. This might be explained because of the required exhaustive application of the linear running time implementations of the operators over terms: $\| \_ \|_f$, $\_(\_)_f$ and $\_[\star \_]_f$ (see Figure 3). This happens since these operators were implemented straightforwardly over tuples that are in fact built as combinations of nominal pairs.

5.2. Upper bounds

Several techniques from [18], originally implemented to deal polynomially with nominal α-equivalence as well as with nominal matching, should be adopted in order to obtain efficient algorithms. Among these techniques, it is necessary to use adequate data structures, such as trees for nominal terms and random access structures for maintaining and answering in constant time queries about the images of permutations and their inverses, as well as for updating compositions of swappings and permutations (and their inverses). The log-linear algorithm defined in [18] to check α-equivalence relies on the

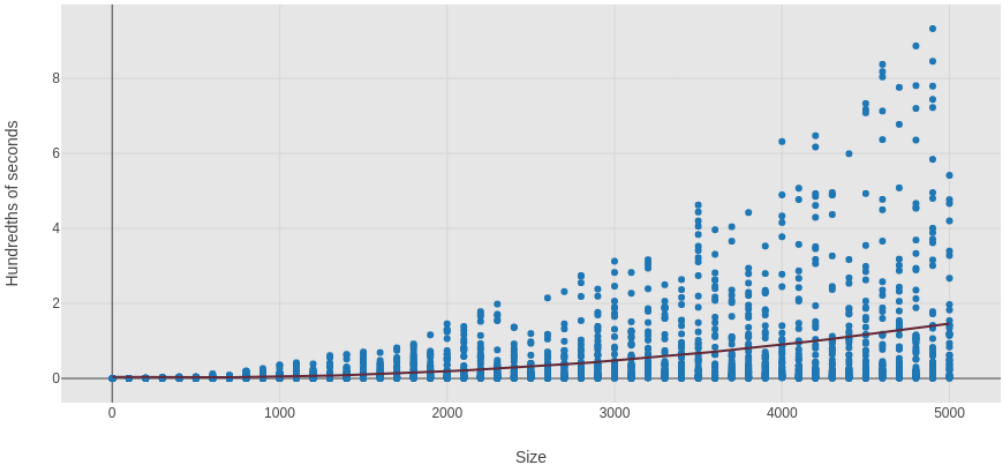

Figure 9: Tests with A function symbols

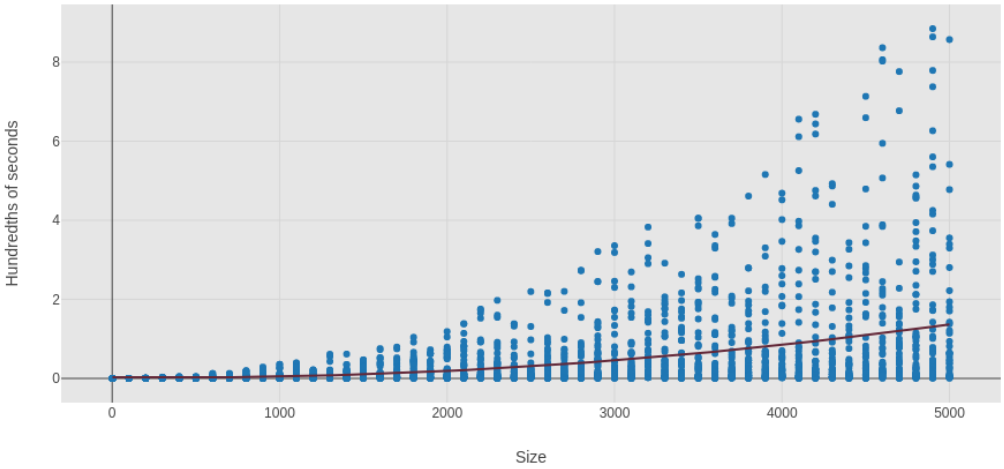

Figure 10: Tests with A and C function symbols

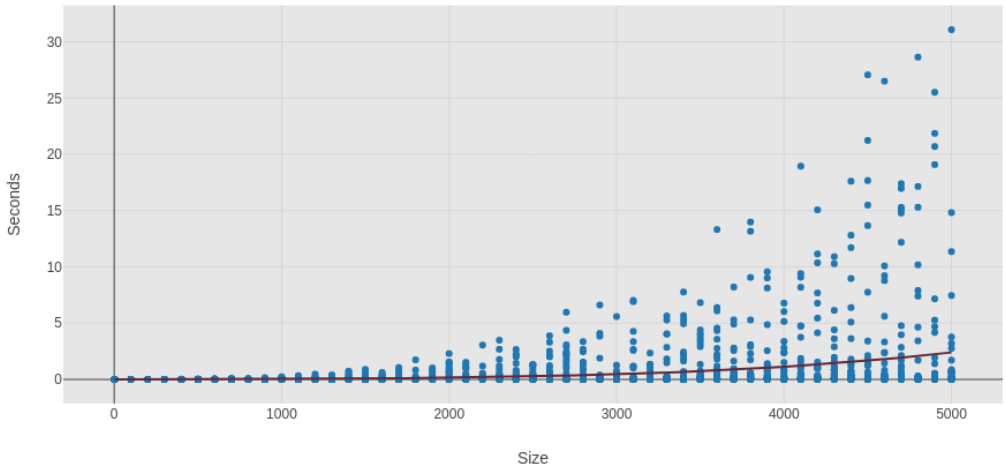

Figure 11: Tests with A, C and AC function symbols

use of "lazy permutations": permutations, their inverses and supports are "suspended" over nominal terms and updated eagerly whenever swappings have to be applied, but they are only pushed down one level in the tree structure of the terms when a transformation rule is applied, and they are applied to terms only when necessary.

Remark 1. *To illustrate why such an approach is used, consider lines 10 to 14 in Algorithm 1, related with the application of the rule* $(\approx_\alpha [\mathbf{ab}])$*. Special care has to be taken with* $(a\ b)\cdot t'$ *(line 12, rule* $(\approx_\alpha [\mathbf{ab}])$*), since it is not a term in our syntax, the permutation has to be propagated in* t' *and this introduces an aditional linear factor on the complexity of checking* α*-equivalence. However, adopting the above-mentioned approach, where the syntax is extended with "suspended" permutations over terms, which are propagated in a "lazy" way, this linear factor is avoided. Also, notice that there is a secondary check for freshness constraints in* $a \# t'$*. This requires an algorithm for validating freshness constraints based on simplification rules for freshness (Fig. 1 bottom up) which is linear in* $\langle \nabla, a \# t' \rangle$*. To avoid repeated computations (for instance, the check for* $a \# t'$ *may appear several times in the computation) one could append valid freshness constraints in* ∇*, that is, line 12 becomes* $\texttt{Check}(\nabla \cup \{a \# t'\}, \{s' \approx (a\,b)t'\} \cup P')$*.*

Theorem 1 (Running time bounds)**.** *Let n be the size of a problem $\langle \nabla, P\rangle$, given as $|\langle \nabla, P\rangle| := |\nabla| + |P|$, where $|\nabla|$ is the number of atoms and variables occurring in ∇ and $|P|$ the sum of the size of terms in equations in P. The validity of $\langle \nabla, P\rangle$ modulo A, C and AC can be checked in time*

i) *$O(n \log n)$, if the problem includes neither C nor AC-function symbols;*
ii) *$O(n^2 \log n)$, if the problem does not contain AC function symbols; and*
iii) *$O(n^4 \log n)$, otherwise.*

Proof. (sketch)

To obtain these bounds we assume first, the use of suspended permutations over terms and of lazy propagation of permutations (see Remark 1); second, that terms in the problems are pre-computed providing a flat representation of the aguments of A-function symbols. For the latter, all maximal subterms that are headed by A-function symbols should be linearly pre-computed to provide their arguments. This can be done for instance using sequences or arrays of terms in which arguments of A-functions are *flattened* and might be accessed randomly (in constant time).

i) Consider a problem of the form $\langle \nabla, \{s \approx t\}\rangle$ where s and t contain neither C- nor AC-function symbols. Since A-function symbols are assumed to be flattened, the problem can be log-lineary solved through a simple adaptation of the solution for α-equivalence checking given in [18]. For the A case, the problem can be directly decomposed, according to the number n_s of flattened arguments, into a new problem with n_s new disjunct equational subproblems, that is, a problem of the form $\langle \nabla, P \cup \{f_k^A s' \approx f_k^A t'\}\rangle$ becomes directly a problem of the form $\langle \nabla, P \cup \{s'_{(1)_{f_k^A}} \approx t'_{(1)_{f_k^A}}, \ldots, s'_{(n_s)_{f_k^A}} \approx t'_{(n_s)_{f_k^A}}\}\rangle$.
ii) Let $\langle \nabla, \{s \approx t\}\rangle$ be a problem without AC-function symbols. A regular worst case happens when the problem has k nested C-function symbols. Assume that $n = m\,2^k$, where $m \ll n$. In this case, if we consider terms with the same commutative symbol at the root, and with arguments of the same size, an upper bound for the running time is given by the recurrence relation:

$$T(n) = 4\,T(n/2) + O(n \log n) \text{ where } T(m) = O(m \log m).$$

In the first recurrence equation, the first summand has a factor 4 because it is necessary to check four sub problems of half of the original size,

and the second summand provides a bound, according to the previous item, if the term does not have C-operators. Notice that both summands are included since the objective is to give an upper bound. The initial condition of the recurrence relation also assumes that subproblems of size m have no occurrences of C-function symbols. Thus one has,

$$\begin{aligned} T(n) &= 4\,T(n/2) + O(n \log n) \\ &= 4^k\,T(m) + O(n)\sum_{i=0}^{k-1} 2^i(\log n - i \log 2) \\ &= (\tfrac{n}{m})^2 O(m \log m) + O(n \log n)\sum_{i=0}^{k-1} 2^i - O(n)\log 2 \sum_{i=0}^{k-1} 2^i i \\ &= O(n^2 \tfrac{\log m}{m}) + O(n \log n)(2^k - 1) - O(n)\log 2(2^k(k-2)+2) \\ &= O(n^2) + O(n^2 \log n) \\ &= O(n^2 \log n) \end{aligned}$$

Factors related with m can be omitted since we assume that $m \ll n$.

iii) First, notice that terms headed by C-function symbols can be considered as a particular case of AC symbols whose tuples (arguments) have always exactly two elements. Thus, the complexity analysis for C- and AC-function symbols could be unified. Let $\langle \nabla, \{s \approx t\}\rangle$ be a problem that contains AC-function symbols. Assuming the flat representation of all maximal subterms of s and t that are headed with A and AC-function symbols is pre-computed, the relevant part of the analysis is related with the verification of α-equivalence between subterms s' and t' of s and t headed by an AC-function symbol, say f_k^{AC}. This involves checking whether the tuple of n_s arguments in s' contains arguments that are related by α-equivalence modulo AC to arguments of the tuple of arguments in t'. These arguments are not necessarily in the same positions in the tuples of arguments of s' and t'. In the worst case scenario, for each argument of the tuple of arguments of f_k^{AC} in s', say $s'_{(i)_{f_k^{AC}}}$, one has to go over the whole tuple of arguments of f_k^{AC} in t', checking $\langle \nabla, \{s'_{(i)_{f_k^{AC}}} \approx t'_{(j)_{f_k^{AC}}}\}\rangle$, for $i, j \leq ||s'||_{f_k^{AC}}$. In case this is true, α-equivalence eliminating these two arguments of the tuples should be ckecked. By item i), one already knows that the procedure without C and AC symbols is log-linear. The problem essentially boils down to the problem of searching a perfect matching in the bipartite graph that consists of vertices V labelled by the n_s arguments of the *lhs*'s and *rhs*'s and edges, E, between vertices labelled with terms that match, as proved in [19] for solving AC-equivalence in the usual first-order syntax. This

problem is known to have solutions of complexity $O(|V| \times |E|)$, that is the same as $O(|V|^3)$ since in the worst case one has $O(|V|^2)$ edges [21]. One concludes that searching for a perfect matching is bounded cubically on the size of the problem, since the number of arguments, $||s'||_{f_k^{AC}}$, is linearly bounded in the size of the problem. Thus, an upper bound for the whole problem is $O(n^4 \log n)$.

□

Remark 2. *Regarding item i), notice that even without function symbols (just atoms, abstractions and tuples) the α-equality check is log-linear for non-ground terms.*

6. Related work

Equational problems have been extensively explored since the early development of modern abstract algebra (see, e.g., the E-unification survey by Baader et al [20]). The treatment given to the problem of deciding AC equality in usual first-order syntax reduces to the problem of searching for a perfect matching in a bipartite graph, as shown in [19].

Further, formalisations about syntactic equational reasoning modulo A, C and AC were explored. Nipkow [22] proposed a set of rewriting tactics in Isabelle/HOL to reasoning modulo A/C/AC. Contejean [23] developed a sound and complete A/C/AC-matching algorithm, that was formalised in Coq and implemented in C*i*ME. Additionally, Braibrant and Pous [24] designed a plugin for Coq to use the tactic `rewrite` modulo AC.

Checking validity of α-equivalence constraints has been studied in [18], where an algorithm to test α-equivalence of nominal terms (both ground or non-ground), derived from a *core algorithm* to solve matching problems modulo α, was provided. The matching algorithm is linear in the size of the problem for the ground case (i.e., when matching a term s against a ground term t) and therefore α-equivalence is also linear in this case. If both terms are non-ground, then α-equivalence is log-linear in the size of the problem, whereas matching is log-linear if the pattern is linear and quadratic otherwise.

Beyond the nominal unification formalisation of Urban et al. [6, 7], there are also other formal nominal developments in Isabelle/HOL, Coq, HOL4, PVS and Agda. For example Aydemir, Bohannon and Weirich developed nominal reasoning techniques in Coq [15]. Urban [16] proposed a framework in Isabelle/HOL that also allows reasoning modulo nominal α-equivalence. This

framework was later extended by Urban and Kaliszyk [16], to admit reasoning in more general binding scopes. Kumar and Norrish [4] presented a nominal unification algorithm that uses *descent recursion* and *triangular substitutions*, with underlying formalisations in HOL4 of the correctness and termination of the proposed algorithm. Ayala-Rincón, Fernández and Rocha-Oliveira [5] formalised in PVS the soundness of the nominal $\approx_\alpha$-equivalence relation, and soundness and completeness of a nominal unification algorithm. Copello et al. [25] presented a nominal approach in a formalisation in Agda of principles of α-structural induction and recursion. Finally, Ayala-Rincón et al. [26] applied this development in order to formalise soundness and completeness of a nominal unification algorithm modulo C.

Nominal narrowing was introduced by Ayala-Rincón, Fernández and Nantes-Sobrinho in [27]. This work adapts Hullot's seminal work on narrowing, originally developed from the first-order rewriting perspective, to the nominal approach in such a manner that nominal equational unification problems are solvable by narrowing whenever the equational theories can be presented as a class of convergent closed rewriting systems.

Another extension of nominal unification was proposed in Schmidt-Schauss et al. [28]. This development proposed an algorithm to solve nominal unification problems with *recursive let* operators. In this algorithm, the solutions of a unification problem are expressed in terms of nominal fixed point equations. Obtaining solutions for such equations is a recurrent problem; indeed, in [26] it was shown that nominal C-unification problems are reduced to solving finite families of fixed point equations. This work also proved that nominal C-unification is infinitary, differing from syntactic C-unification that is well-known to be finitary. Afterwards, in [29], Ayala-Rincón et al. proposed a sound and complete combinatorial procedure to generate the set of solutions of nominal fixed point problems.

A few distinguishing elements of nominal formalisation developments are listed below.

- The current Coq formalisation, as the Isabelle/HOL formalisation of nominal unification in [7, 6], inductively specifies equational procedures as sets of inference rules. These sets are given through inductive predicates, which allow the proof assistants to build inductive proof schemes on the predicates in a straightforward manner. In our approach, this resulted also convenient, since providing a sole inductive definition in which all inference rules are included allows for a modular treatment

of equational check modulo different equational properties (such as A/C/AC) and their combinations.

- In contrast to the inductive approaches used in our Coq development and the Isabelle/HOL referenced approach, the HOL4 and PVS formalisations of nominal unification in [4] and [5], respectively, use a recursive style to specify unification algorithms. In these developments inductive proofs are guided by smart termination measures provided as part of the specification. In the PVS development a first-order functional algorithm *à la* Robinson which has as parameter only nominal terms is verified. Avoiding freshness constraints as parameters is one of the disthinguishing features of this PVS formalisation, that is possible due to the formalisation of properties on the independence of freshness contexts regarding substitutions in solutions. The HOL4 formalisation specifies triangular substitutions that are sets of singleton bindings for different variables used to present unification in an accumulator-passing style, in which in the execution of each recursive call a substitution is taken as input returning an extension on success. Both of these recursive specifications allow extraction of recursive unification functions, but they do not allow the modularity of the inductive approaches in which new inference rules can be added and fragments of the previous correctness proofs (concerning the analysis of cases related with previous existing inference rules) can be reused.

7. Conclusion and Future Work

The soundness of nominal α-equivalence and its extension to the equational theories A, C, AC and their combinations were formalised in Coq.

Checking soundness of these relations required checking that they are specified in such a manner that they are indeed equivalence relations. In particular, the property of transitivity for $\approx_\alpha$ was formalised in a direct manner without using an auxiliary weak intermediate relation as done in [4], [6] and [17]. The proof of transitivity follows the approach introduced in [5] for formalising nominal unification in PVS. Here, the proof is based on elementary lemmas about permutations, freshness and α-equivalence; such lemmas are well-known in the context of nominal unification. In [6], the same auxiliary lemmas to demonstrate transitivity were proved, including some extra lemmas to deal with this weak-equivalence. The current formalisation

of transitivity of $\approx_\alpha$ is simpler in the sense that it only uses the essential notions and results. Indeed, adopting the direct approach in [5] resulted in a more compact formalisation with several improvements, among them a formalisation of symmetry of $\approx_\alpha$ that is independent from transitivity, diverging from the approach that uses weak equivalence, where it is obtained as a consequence of transitivity.

The grammar of nominal terms was specified in such a way that in addition to A, C and AC rules one can easily add other inference rules to express properties such as *idempotency* (I), *neutral* (U) and *inverse* elements (**G**roup theory), and their combinations A, AC, AI, ACI, ACU, ACUI, etc.

Enriching nominal α-equality with equational theories formally, will provide an effective framework for dealing not only with nominal α-equivalence, but also with other related fundamental relations such as nominal *matching*, *unification* and *narrowing* in concrete applications. Examples of such applications can be found in several contexts, such as the one of integrity of cryptographic protocols [27, 30, 31]. A further interesting analysis would be the classification of the related problems of nominal α-matching and unification modulo theories, regarding their complexities.We have started this investigation with the case of α-unification modulo C in [26, 29] and we are currently implementing efficient versions of the α-equivalence decision algorithm to use within a nominal matching algorithm modulo A, C and AC theories.

Appendix A. Explanation of the improvements with respect to the papers [17] and [5]

The main improvements over the previous two papers from LSFA 2015 and 2016 are summarised here.

- The Coq formalisation of transitivity of the relation $\approx_\alpha$ adopts now the direct method introduced in the PVS formalisation of nominal α-unification presented in our LSFA 2015 paper ([5]). This approach avoids the use of an auxiliary weak equivalence $\sim_\omega$, as introduced in the HOL4 formalisation in [4] and adopted in the Isabelle/HOL formalisation in [6] , which was the original method formalised in Coq in our LSFA 2016 paper ([17]). As detailed in Section 3, the more direct approach used in the current paper gives the specific benefits listed below.

  - A shorter formalisation, since a series of auxiliary lemmas on $\sim_\omega$ are no longer necessary.
  - Also, intermediate transitivity lemmas relating $\sim_\omega$ and $\approx_\alpha$ are no longer necessary.
  - The direct approach required only a few new auxiliary lemmas on $\approx_\alpha$ that are proved by simple induction on terms and the inductive definition of the α-equality inference rules.
  - It is also important to stress that despite the fact that the current formalisation of the lemma of transitivity of $\approx_\alpha$ is now based only on nominal properties and basic properties of $\approx_\alpha$, this proof is not more complex than the previous one, being the number of proof lines almost the same.
  - The current proof of symmetry of $\approx_\alpha$ is independent of transitivity. The former approach has the drawback of having a formalisation of symmetry obtained as a consequence of transitivity.

- In this version separated treatment of C-operators was included as mentioned in Section 4.1. This required the addition of the commutative case for dealing with the commutative operators and associated rules in formalisations of lemmas on intermediate transitivity for $\approx_{\{A,C,AC\}}$, freshness preservation under $\approx_{\{A,C,AC\}}$, equivariance, reflexivity, symmetry and transitivity of $\approx_{\{A,C,AC\}}$ and combination of AC arguments

(Lemmas 9 to 15, among others). This was essential for the specification of a verified nominal C-unification procedure and the study of nominal fixed point problems presented respectively in [29] and [26] referenced in the subsection on related work in the introduction.

- An OCaml implementation of an algorithm extracted from the rules was developed, and simple randomly generated equational problems were used to test the algorithm. The analysis of upper bounds was extended in order to include the case of checking nominal equivalence with syntactic, A and AC-operators combined with C-operators (Theorem 1).
